Summary

Melanocytic nevi, commonly known as moles, are usually harmless skin growths that can vary in color and size. They are formed by clusters of melanocytes, the cells that produce pigment in the skin.

What is this condition?

A melanocytic nevus is a benign (non-cancerous) skin lesion that appears as a small, dark spot on the skin. These moles can be flat or raised and may be present at birth or develop over time.

Why does it happen?

Moles are caused by the growth of melanocytes, which can be influenced by genetic factors and sun exposure. Some people may have more moles due to their family history or skin type.

Symptoms

- Small, dark spots on the skin
- Can be flat or raised
- May vary in color from brown to black
- Generally round or oval in shape
- Usually painless and non-itchy

Self-Care Tips

- Protect your skin from sun exposure with sunscreen
- Avoid tanning beds
- Monitor your moles for any changes
- Keep your skin moisturized
- Practice good skin hygiene

Red Flags — Warning Signs

- A mole that changes in size, shape, or color
- Moles that become itchy or bleed
- New moles appearing after age 30
- Moles that have an irregular border
- Multiple moles that look different from each other

When to Seek Medical Care

- If you notice changes in an existing mole
- If you develop new moles that look unusual
- If a mole becomes painful or inflamed
- If you have a family history of skin cancer
- If you have concerns about your skin

Recommended Next Steps

- Schedule an appointment with a qualified dermatologist
- Bring a list of any changes you've noticed
- Take photos of your moles for reference
- Discuss any family history of skin conditions
- Follow your dermatologist's recommendations for skin care
